"5 hours after the bedside transfusion the kid was still under the influence of the toxin. He never said a word to his parents, never cried, never wanted to be held. He just sat in his bed, watched his belly get bigger and bigger every hour and waited for death." "In the first hours of life, babies are susceptible to the effects of intra-uterine infection and exposure to alcohol. Babies born by C-section are more likely to have a serious infection." "In the US, 30,000 babies are born every year with intrauterine infections acquired from their mother. The major cause is early infection by Chlamydia trachomatis. Some forms of this infection are not usually diagnosed until delivery, and may lead to damage to the baby." "The words'mother to child transmission' are scary to many because they suggest that mother and baby are vulnerable to each other. Actually, the risk of vertical transmission of the parasite is very small and is concentrated during birth. If the mother has chlamydia, she may transmit the infection to her baby before or after birth, and, in a few days or weeks, the baby will develop chlamydial pneumonia (acute respiratory tract infection). The infection may cause mild to severe respiratory symptoms, especially in infants and young children." "The CDC has recommended that all pregnant women in the United States be screened for chlamydial infection because these infections are highly treatable if diagnosed early. But the screening tests to look for chlamydial infection have low accuracy." "The cost of treating chlamydial infection is estimated at $1.3 billion annually, primarily because of the complications associated with secondary infection. The economic burden of this disease is especially high in areas with high incidence rates because of the high rate of infertility and the difficulty in treating the diseases." Predominance of Sporadic PML/RARA Translocations in Relapsed Acute Promyelocytic Leukemia. Acute promyelocytic leukemia (APL) is characterized by the t(15;17)(q24;q21) translocation resulting in fusion of promyelocytic leukemia (PML) gene on chromosome 15 and retinoic acid receptor alpha (RARA) gene on chromosome 17. We analyzed clonal karyotypes in 69 patients who relapsed from complete remission after first-line therapy and detected 65 clonal karyotypes. The chromosomal abnormalities of clonal karyotypes, included loss of the Y chromosome, monosomy 17, and trisomy 8. Trisomy 8 was the most common, present in 63% (41/65). Moreover, we observed a second PML/RARA translocation in 2 patients, both in their first relapse. Only 6 cases showed the classical t(15;17)(q24;q21). All these cases showed recurrent cytogenetic abnormalities including monosomy 17, trisomy 8, and loss of Y chromosome, indicating that clonal evolution occurred in patients with APL. In conclusion, we observed a high frequency of PML/RARA translocations in patients relapsed from APL. These results may suggest that the majority of APL clones at relapse are derived from preexisting APL clones. The significance of other clonal karyotypes, including trisomy 8 and monosomy 17, observed in recurrent APL, should be further investigated.Inhibitory effects of methylglyoxal on nerve conduction velocity in the rat sciatic nerve. Sciatic nerve conduction velocity (SCV) in the rat decreases with age. In the present study, methylglyoxal (MG) was examined for its effect on SCV in the sciatic nerve in rats of different ages. MG at different doses was injected into the right sciatic nerve of rats. The effect of MG on SCV was measured in the sciatic nerve. The amount of MG in the sciatic nerve was also measured. In all the young rats, the SCV decreased significantly to a maximum of 77% after injection of the MG. The effect of MG lasted for three days, and then decreased. The amount of MG in the sciatic nerve was lower in the older rats than in the young rats.
